# Summary

- Searching
  - Sequential search
  - Binary search
- Sorting
- Functions as arguments
- Lambda expressions

Fundamentos de Programação 2017/2018

departamento de electrónica,  
telecomunicações e informática

# Searching

- Searching for an element  $X$  in a list  $L$  (or some other sequence) is a common operation in many problems.
  - Sometimes we just need to check if the element is there. (\*)  
In Python, we can do this with: `X in L`
  - Other times we need to know where it is.  
In Python, we can do this with: `L.index(X)`
- These operations are simple, but they can be **expensive**: it takes time (and energy) to search a very large list!  
(\*) Note that if all we need is checking membership, then using a set or a dictionary is much faster than a list!

Fundamentos de Programação 2017/2018

departamento de electrónica,  
telecomunicações e informática

# Sequential search

- A **sequential search** scans a list from start to end (or the from the end to the start).

```
def seqSearch(lst, x):  
    """Return k such that x == lst[k], or None if no such k."""  
    for i in range(len(lst)):  
        if x == lst[i]:  
            return i  
    return None
```

- This is what the list `index` method and the `in` operator do.
- Finding an element in a list of length  $N$  requires up to  $N$  comparisons.

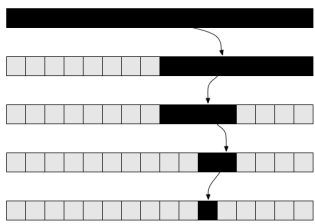

Fundamentos de Programação 2017/2018

## Binary search

deti universidade de aveiro  
departamento de electrónica,  
telecomunicações e informática

- If the list is sorted,  $L[0] \leq L[1] \leq \dots \leq L[-1]$ , there's a much better way to search!
  - Compare  $X$  to the middle element of  $L$ .
  - If  $X$  is smaller, search only in the first half of  $L$ .
  - If  $X$  is larger, search only in the second half.
- This is the **binary search** algorithm.
- This is much better:
  - $N=15 \Rightarrow$  just 4 comparisons.
  - $N=31 \Rightarrow$  5 comparisons
  - $N \sim 1$  thousand  $\Rightarrow$  10 comparisons.
  - $N \sim 1$  million  $\Rightarrow$  20 comparisons!
- If  $N < 2^k \Rightarrow k$  comparisons.

Fundamentos de Programação 2017/2018

## Binary search (2)

deti universidade de aveiro  
departamento de electrónica,  
telecomunicações e informática

- Binary search for exact match (stops when equal).

```
def binSearchExact(lst, x):
    """Find k such that x == lst[k]. (Or None if no such k.)"""
    first = 0          # first index that could be solution
    last = len(lst)    # first index that cannot be solution
    while first < last:
        mid = (first+last)//2
        if x < lst[mid]:
            last = mid
        elif x > lst[mid]:
            first = mid+1
        else:
            return mid
    return None
```

- This works exactly like seqSearch, but much faster!
- But we can make it faster yet, with a minor modification.

Fundamentos de Programação 2017/2018

## Binary search (3)

deti universidade de aveiro  
departamento de electrónica,  
telecomunicações e informática

- Binary search. (Equivalent to `bisect.bisect_left`.)

```
def binSearch(lst, x):
    """Find k such that: lst[k-1] < x <= lst[k] (not quite!)."""
    first = 0          # first index that can be result
    last = len(lst)    # last index that can be result
    while first < last:
        mid = (first+last)//2
        if x <= lst[mid]: # (just 1 comparison inside loop!)
            last = mid
        else:
            first = mid+1
    return first
```

- If  $x$  is not found, still returns index  $k$  of where  $x$  should be!
- If  $k < \text{len}(\text{lst})$  and  $x == \text{lst}[k]$ , then we know  $x$  was found.
- This is slightly faster, in general.

Fundamentos de Programação 2017/2018

## Sorting

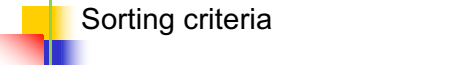

deti universidade de aveiro  
departamento de electrónica,  
telecomunicações e informática

- A sorted list is much faster to search.
- Sorting is putting the elements of a list in order.
- In Python, use the `sorted` function or the list `sort` method.
 

```
L.sort()          # Modifies L in-place
L2 = sorted(L)    # Creates L2. L is not modified!
```
- `sorted` returns a list, but takes any kind of collection.
 

```
sorted('banana')  #-> ['a', 'a', 'a', 'b', 'n', 'n']
L = [9, 7, 2, 8, 5, 3]
print(sorted(L))   #-> [2, 3, 5, 7, 8, 9]
L = ["maria", "carla", "anabela", "antonio", "nuno"]
print(sorted(L))
#-> ['anabela', 'antonio', 'carla', 'maria', 'nuno']
```

Fundamentos de Programação 2017/2018

## Sorting criteria

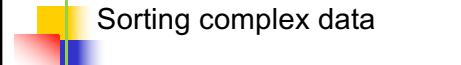

universidade de aveiro  
departamento de electrónica,  
telecomunicações e informática

- These functions can sort by different criteria.
 

```
L = ["Mario", "Carla", "anabela", "Maria", "nuno"]
print(sorted(L)) # lexicographic sort
#-> ['Carla', 'Maria', 'Mario', 'anabela', 'nuno']
print(sorted(L, key=len)) # sort by length
#-> ['nuno', 'Mario', 'Carla', 'Maria', 'anabela']
print(sorted(L, key=str.lower))
#-> ['anabela', 'Carla', 'Maria', 'Mario', 'nuno']
```
- The optional `key` argument receives a function to sort the elements by.
- The key function is applied to each element and results are compared.
- There is also a `reversed` optional argument.

Fundamentos de Programação 2017/2018

## Sorting complex data

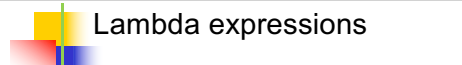

universidade de aveiro  
departamento de electrónica,  
telecomunicações e informática

- Lists of tuples can be sorted, too.
 

```
dates = [(1910, 10, 5, 'Republic'),
          (1974, 4, 25, 'Liberty'),
          (1640, 12, 1, 'Independence')]
print(sorted(dates)) # "lexicographic" order
```
- Tuples are compared like strings: left-to-right.
- For a different order, use the `key` argument.
 

```
sorted(dates, key=lambda t: t[3]) #by name
sorted(dates, key=lambda t: (t[1],t[2])) #by month,day
```
- We're using lambda expressions here!

Fundamentos de Programação 2017/2018

## Lambda expressions

universidade de aveiro  
departamento de electrónica,  
telecomunicações e informática

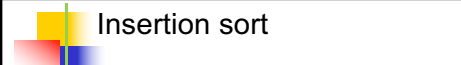

- Lambda expressions** are define anonymous functions.
 

```
sq = lambda x: x**2
sq(5) #-> 25
add = lambda x,y: x+y
```

# Same as:
def sq(x):
 return x\*\*2
- Result must be an expression. No statements allowed!
- Should only be used for simple functions.
- They're useful to pass as arguments (such as `key=...`).
- Exercise: use a lambda expression to sort names by length, then alphabetically.
 

```
sorted(L, key=lambda s: (len(s),s))
#-> ['nuno', 'Carla', 'Maria', 'Mario', 'anabela']
```

Fundamentos de Programação 2017/2018

## Insertion sort

universidade de aveiro  
departamento de electrónica,  
telecomunicações e informática

- The insertion sort algorithm:
  - Assume the first  $K$  elements are sorted.  $L[K]$  is not.
  - Save  $L[K]$  in  $T$ .
  - Move every  $L[J]>T$  to  $L[J+1]$ , starting from  $J=K-1$  down.
  - Put  $T$  into the vacant slot.
  - Now, increment  $K$  and repeat.
